epca-package

Exploratory Principal Component Analysis

## Description

epca is for comprehending any data matrix that contains *low-rank* and *sparse* underlying signals of interest. The package currently features two key tools: (1) sca for sparse principal component analysis and (2) sma for sparse matrix approximation, a two-way data analysis for simultaneously row and column dimensionality reductions.

## References

Chen, F. and Rohe K. (2020) "A New Basis for Sparse PCA".

absmin

## Description

Given a p x k matrix x, finds the orthogonal matrix (rotation) that minimizes the absmin.criteria.

## Usage

```
absmin(x, r0 = diag(ncol(x)), normalize = FALSE, eps = 1e-05, maxit = 1000L)
```

## Arguments

х	a matrix or Matrix, initial factor loadings matrix for which the rotation criterian is to be optimized.
r0	matrix, initial rotation matrix.
normalize	logical. Should Kaiser normalization be performed? If so the rows of x are re-scaled to unit length before rotation, and scaled back afterwards.
eps	The tolerance for stopping: the relative change in the sum of singular values.
maxit	integer, maximum number of iteration (default to 1,000).

## Value

A list with three elements:

rotated	the rotated matrix.
rotmat	the (orthogonal) rotation matrix.
n.iter	the number of iteration taken.

## See Also

GPArotation::GPForth

n Criteria
------------

## Description

Calculate the absmin criteria. This is a helper function for absmin.

## Usage

absmin.criteria(x)

## Arguments

Х

a matrix or Matrix, initial factor loadings matrix for which the rotation criterian is to be optimized.

cpve

Cumulative Proportion of Variance Explained (CPVE)

## Description

Calculate the CPVE.

## Usage

cpve(x, v, is.cov = FALSE)

### Arguments

х	matrix or Matrix, the original data matrix or the Gram matrix.
v	matrix or Matrix, coefficients of linear transformation, e.g., loadings (in PCA).
is.cov	logical, whether the input matrix is a covariance matrix (or a Gram matrix).

## Value

a numeric vector of length ncol(v), the i-th value is the CPVE of the first i columns in v.

## See Also

pve

## Examples

```
## use the "swiss" data
## find two sparse PCs
s.sca <- sca(swiss, 2, gamma = sqrt(ncol(swiss)))
ld <- loadings(s.sca)
cpve(as.matrix(swiss), ld)</pre>
```

dist.matrix

#### Description

Compute the distance between two matrices. The distance between two matrices is defined as the sum of distances between column pairs. This function matches the columns of two matrices, such that the matrix distance (i.e., the sum of paired column distances) is minimized. This is accomplished by solving an optimization over column permutation. Given two matrices, x and y, find permutation p() that minimizes sum\_i similarity(x[,p(i)], y[,i]), where the similarity() can be "euclidean" distance, 1 - "cosine", or "maximum" difference (manhattan distance). The solution is computed by clue::solve\_LSAP().

#### Usage

dist.matrix(x, y, method = "euclidean")

## Arguments

х, у	matrix or Matrix, of the same number of rows. The columns of x and y will be
	scaled to unit length.
method	distance measure, "maximum", "cosine", or "euclidean" are implemented.

## Value

a list of four components:

dist	dist, the distance matrix.
match	solve_LSAP, the column matches.
value	numeric vector, the distance between pairs of columns.
method	character, the distance measure used.
nrow	integer, the dimension of the input matrices, i.e., $nrow(x)$ .

### See Also

clue::solve\_LSAP

## Examples

```
x <- diag(4)
y <- x + rnorm(16, sd = 0.05) # add some noise
y = t(t(y) / sqrt(colSums(y ^ 2))) ## normalize the columns
## euclidian distance between column pairs, with minimal matches
dist.matrix(x, y, "euclidean")
```

distance

## Description

Matrix Distance

## Usage

distance(x, y, method = "euclidean")

## Arguments

х, у	matrix or Matrix, of the same number of rows. The columns of x and y will be scaled to unit length.
method	distance measure, "maximum", "cosine", or "euclidean" are implemented.

## Value

numeric, the distance between two matrices.

exp.frac

Calculate fractional exponent/power

## Description

Calculate fractional exponent/power, a^(num/den), where a could be negative.

## Usage

## S3 method for class 'frac'
exp(a, num, den)

## Arguments

а	numeric(1), base (could be negative).
num	a positive integer, numerator of the exponent.
den	a positive integer, denominator of the exponent.

## Value

numeric, the evaluated a^(num/den)

hard

## Description

Perform hard-thresholding given the cut-off value.

## Usage

hard(x, t)

## Arguments

х	any numerical matrix or vector.
t	numeric, the amount to hard-threshold, i.e., $sgn(x_{ij})( x_{ij}-t )_+$ .

1	nner	

Matrix Inner Product

## Description

Calculate the custom matrix inner product z of two matrices, x and y, where z[i,j] = FUN(x[,i], y[,j]).

## Usage

inner(x, y, FUN = "crossprod", ...)

## Arguments

х, у	matrix or Matrix.
FUN	<pre>function or a character(1) name of base function. The function should take in two vectors as input and output a numeric(1) result.</pre>
	additional parameters for FUN.

## Value

matrix, inner product of x and y.

## Examples

```
x <- matrix(1:6, 2, 3)
y <- matrix(7:12, 2, 3)
## The default is equivalent to `crossprod(x, y)`
inner(x, y)
## We can compute the pair-wise Euclidean distance of columns.
EuclideanDistance = function(x, y) crossprod(x, y)^2
inner(x, y, EuclideanDistance)
```

labelCluster Label Cluster

## Description

Assign cluster labels to each row from the membership matrix.

## Usage

labelCluster(x, ties.method = "random")

#### Arguments

X	matrix with non-negative entries, where x[i,j] is the estimated likelihood (or any equivalent measure) of node i belongs to block j. The higher the more likely.
ties.method	character, how should ties be handled, "random", "first", "last" are allowed. See base::rank() for details.

#### Value

integer vector of the same length as x. Each entry is one of 1, 2, ..., ncol(x).

misClustRate Mis-Classification Rate (MCR)

## Description

Compute the empirical MCR, assuming that #cluster = #block, This calculation allows a permutation on clusters.

## Usage

```
misClustRate(cluster, truth)
```

#### 8

## norm.Lp

## Arguments

cluster	vector of integer or factor, estimated cluster membership.
truth	a vector of the same length as clusters, the true cluster labels.

## Value

numeric, the MCR.

## Examples

```
truth = rep(1:3, each = 30)
cluster = rep(3:1, times = c(25, 32, 33))
misClustRate(cluster, truth)
```

norm.Lp

## Element-wise Matrix Norm

## Description

Compute element-wise matrix Lp-norm. This is a helper function to shrinkage().

## Usage

norm.Lp(x, p = 1)

## Arguments

х	a matrix or Matrix.
р	numeric(1), the p for defining the Lp norm.

## Value

numeric(1), the absolute sum of all elements.

permColumn

## Description

Perform column permutation of block membership matrix for aesthetic visualization. That is, the k-th column gives k-th cluster. This is done by ranking the column sums of squares (by default).

## Usage

permColumn(x, s = 2)

#### Arguments

х	a non-negative matrix, nNode x nBlock,
S	integer, order of non-linear

pitprops

Pitprops correlation data

#### Description

The pitprops data is a correlation matrix that was calculated from 180 observations. There are 13 explanatory variables. Jeffers (1967) tried to interpret the first six PCs. This is a classical example showing the difficulty of interpreting principal components.

#### References

Jeffers, J. (1967) "Two case studies in the application of principal component", *Applied Statistics*, 16, 225-236.

## Examples

```
## NOT TEST
data(pitprops)
ggcorrplot::ggcorrplot(pitprops)
```

polar

#### Description

Perform the polar decomposition of an n x p (n > p) matrix x into two parts: u and h, where u is an n x p unitary matrix with orthogonal columns (i.e. crossprod(u) is the identity matrix), and h is a p x p positive-semidefinite Hermitian matrix. The function returns the u matrix. This is a helper function of prs().

#### Usage

polar(x)

## Arguments

Х

a matrix or Matrix, which is presumed full-rank.

## Value

a matrix of the unitary part of the polar decomposition.

## References

Chen, F. and Rohe, K. (2020) "A New Basis for Sparse Principal Component Analysis."

## Examples

x <- matrix(1:6, nrow = 3)
polar\_x <- polar(x)</pre>

print.sca

Print SCA

#### Description

Print SCA

## Usage

## S3 method for class 'sca'
print(x, verbose = FALSE, ...)

#### Arguments

х	an sca object.
verbose	logical(1), whether to print out loadings.
	additional input to generic print.

## Value

Print an sca object interactively.

## Description

Print SMA

## Usage

```
## S3 method for class 'sma'
print(x, verbose = FALSE, ...)
```

## Arguments

x	an sma object.
verbose	logical(1), whether to print out loadings.
	additional input to generic print.

#### Value

Print an sma object interactively.

prs

Polar-Rotate-Shrink

## Description

This function is a helper function of sma(). It performs polar docomposition, orthogonal rotation, and soft-thresholding shrinkage in order. The three steps together enable sparse estimates of the SMA and SCA.

## Usage

```
prs(x, z.hat, gamma, rotate, shrink, normalize, order, flip, epsilon)
```

#### Arguments

x,z.hat	the matrix product crossprod(x, z.hat) is the actual Polar-Rotate-Shrink object. x and z.hat are input separatedly because the former is additionally used to compute the proportion of variance explained, in the case when order = TRUE.
gamma	numeric, the sparsity parameter.
rotate	character(1), rotation method. Two options are currently available: "varimax" (default) or "absmin" (see details).
shrink	character(1), shrinkage method, either "soft"- (default) or "hard"-thresholding (see details).
normalize	logical, whether to rows normalization should be done before and undone af- terward the rotation (see details).
order	logical, whether to re-order the columns of the estimates (see Details below).
flip	logical, whether to flip the signs of the columns of estimates such that all columns are positive-skewed (see details).
epsilon	numeric, tolerance of convergence precision (default to 0.00001).

#### Details

rotate: The rotate option specifies the rotation technique to use. Currently, there are two build-in options—"varimax" and "absmin". The "varimax" rotation maximizes the element-wise L4 norm of the rotated matrix. It is faster and computationally more stable. The "absmin" rotation minimizes the absolute sum of the rotated matrix. It is sharper (as it directly minimizes the L1 norm) but slower and computationally less stable.

shrink: The shrink option specifies the shrinkage operator to use. Currently, there are two build-in options—"soft"- and "hard"-thresholding. The "soft"-thresholding universally reduce all elements and sets the small elements to zeros. The "hard"-thresholding only sets the small elements to zeros.

normalize: The argument normalize gives an indication of if and how any normalization should be done before rotation, and then undone after rotation. If normalize is FALSE (the default) no normalization is done. If normalize is TRUE then Kaiser normalization is done. (So squared row entries of normalized x sum to 1.0. This is sometimes called Horst normalization.) For rotate="absmin", if normalize is a vector of length equal to the number of indicators (i.e., the number of rows of x), then the columns are divided by normalize before rotation and multiplied by normalize after rotation. Also, If normalize is a function then it should take x as an argument and return a vector which is used like the vector above.

order: In PCA (and SVD), the principal components (and the singular vectors) are ordered. For this, we order the sparse components (i.e., the columns of z or y) by their explained variance in the data, which is defined as  $sum((x \%\% y)^2)$ , where y is a column of the sparse component. Note: not to be confused with the cumulative proportion of variance explained by y (and z), particularly when y (and z) is may not be strictly orthogonal.

flip: The argument flip gives an indication of if and the columns of estimated sparse component should be flipped. Note that the estimated (sparse) loadings, i.e., the weights on original variables, are column-wise invariant to a sign flipping. This is because flipping of a principal direction does not influence the amount of the explained variance by the component. If flip=TRUE, then the columns of loadings will be flip accordingly, such that each column is positive-skewed. This means that for each column, the sum of cubic elements (i.e., sum(x^3)) are non-negative.

## Value

a matrix of the sparse estimate, of the same dimension as crossprod(x, z.hat).

## References

Chen, F. and Rohe, K. (2020) "A New Basis for Sparse Principal Component Analysis."

#### See Also

sma, sca, polar, rotation, shrinkage

pve

Proportion of Variance Explained (PVE)

#### Description

Calculate the Proportion of variance explained by a set of linear transformation, (e.g. eigenvectors).

#### Usage

pve(x, v, is.cov = FALSE)

## Arguments

х	matrix or Matrix, the original data matrix or the Gram matrix.
v	matrix or Matrix, coefficients of linear transformation, e.g., loadings (in PCA).
is.cov	logical, whether the input matrix is a covariance matrix (or a Gram matrix).

#### Value

a numeric value between 0 and 1, the proportion of total variance in x explained by the PCs whose loadings are in v.

#### References

Shen, H., & Huang, J. Z. (2008). "Sparse principal component analysis via regularized low rank matrix approximation." *Journal of multivariate analysis*, 99(6), 1015-1034.

## Examples

```
## use the "swiss" data
## find two sparse PCs
s.sca <- sca(swiss, 2, gamma = sqrt(ncol(swiss)))
ld <- loadings(s.sca)
pve(as.matrix(swiss), ld)</pre>
```

rootmatrix

## Description

Find the root matrix (x) from the Gram matrix (i.e., crossprod(x)). This is also useful when the input is a covariance matrix, up to a scaling factor of n-1, where n is the sample size.

## Usage

rootmatrix(x)

## Arguments

Х

a symmetric matrix (will trigger error if not symmetric).

rotation	Varimax Rotation		
----------	------------------	--	--

## Description

Perform varimax rotation. Flip the signs of columns so that the resulting matrix is positive-skewed.

#### Usage

```
rotation(
    x,
    rotate = c("varimax", "absmin"),
    normalize = FALSE,
    flip = TRUE,
    eps = 1e-06
)
```

## Arguments

х	a matrix or Matrix.
rotate	character(1), rotation method. Two options are currently available: "varimax" (default) or "absmin" (see details).
normalize	logical, whether to rows normalization should be done before and undone af- terward the rotation (see details).
flip	logical, whether to flip the signs of the columns of estimates such that all columns are positive-skewed (see details).
eps	numeric precision tolerance.

#### Details

16

rotate: The rotate option specifies the rotation technique to use. Currently, there are two build-in options—"varimax" and "absmin". The "varimax" rotation maximizes the element-wise L4 norm of the rotated matrix. It is faster and computationally more stable. The "absmin" rotation minimizes the absolute sum of the rotated matrix. It is sharper (as it directly minimizes the L1 norm) but slower and computationally less stable.

normalize: The argument normalize gives an indication of if and how any normalization should be done before rotation, and then undone after rotation. If normalize is FALSE (the default) no normalization is done. If normalize is TRUE then Kaiser normalization is done. (So squared row entries of normalized x sum to 1.0. #### See Also

prs, varimax

#### Examples

```
## use the "swiss" data
fa <- factanal( ~., 2, data = swiss, rotation = "none")
rotation(loadings(fa))</pre>
```

```
sca
```

#### Sparse Component Analysis

#### Description

sca performs sparse principal components analysis on the given numeric data matrix. Choices of rotation techniques and shrinkage operators are available.

Usage

```
sca(
 х,
 k = min(5, dim(x)),
 gamma = NULL,
 is.cov = FALSE,
 rotate = c("varimax", "absmin"),
 shrink = c("soft", "hard"),
 center = TRUE,
  scale = FALSE,
 normalize = FALSE,
 order = TRUE,
 flip = TRUE,
 max.iter = 1000,
 epsilon = 1e-05,
 quiet = TRUE
)
```

## Arguments

x	matrix or Matrix to be analyzed.
k	integer, rank of approximation.
gamma	numeric(1), sparsity parameter, default to $sqrt(pk)$ , where n x p is the dimension of x.
is.cov	logical, default to FALSE, whether the x is a covariance matrix (or Gram matrix, i.e., crossprod() of some design matrix). If TRUE, both center and scale will be ignored/skipped.
rotate	character(1), rotation method. Two options are currently available: "varimax" (default) or "absmin" (see details).
shrink	character(1), shrinkage method, either "soft"- (default) or "hard"-thresholding (see details).
center	logical, whether to center columns of x (see scale()).
scale	logical, whether to scale columns of x (see scale()).
normalize	logical, whether to rows normalization should be done before and undone afterward the rotation (see details).
order	logical, whether to re-order the columns of the estimates (see Details below).
flip	logical, whether to flip the signs of the columns of estimates such that all columns are positive-skewed (see details).
max.iter	integer, maximum number of iteration (default to 1,000).
epsilon	numeric, tolerance of convergence precision (default to 0.00001).
quiet	logical, whether to mute the process report (default to TRUE)

sca

#### Details

rotate: The rotate option specifies the rotation technique to use. Currently, there are two build-in options—"varimax" and "absmin". The "varimax" rotation maximizes the element-wise L4 norm of the rotated matrix. It is faster and computationally more stable. The "absmin" rotation minimizes the absolute sum of the rotated matrix. It is sharper (as it directly minimizes the L1 norm) but slower and computationally less stable.

shrink: The shrink option specifies the shrinkage operator to use. Currently, there are two build-in options—"soft"- and "hard"-thresholding. The "soft"-thresholding universally reduce all elements and sets the small elements to zeros. The "hard"-thresholding only sets the small elements to zeros.

normalize: The argument normalize gives an indication of if and how any normalization should be done before rotation, and then undone after rotation. If normalize is FALSE (the default) no normalization is done. If normalize is TRUE then Kaiser normalization is done. (So squared row entries of normalized x sum to 1.0. This is sometimes called Horst normalization.) For rotate="absmin", if normalize is a vector of length equal to the number of indicators (i.e., the number of rows of x), then the columns are divided by normalize before rotation and multiplied by normalize after rotation. Also, If normalize is a function then it should take x as an argument and return a vector which is used like the vector above.

order: In PCA (and SVD), the principal components (and the singular vectors) are ordered. For this, we order the sparse components (i.e., the columns of z or y) by their explained variance in the data, which is defined as  $sum((x \%\% y)^2)$ , where y is a column of the sparse component. Note: not to be confused with the cumulative proportion of variance explained by y (and z), particularly when y (and z) is may not be strictly orthogonal.

flip: The argument flip gives an indication of if and the columns of estimated sparse component should be flipped. Note that the estimated (sparse) loadings, i.e., the weights on original variables, are column-wise invariant to a sign flipping. This is because flipping of a principal direction does not influence the amount of the explained variance by the component. If flip=TRUE, then the columns of loadings will be flip accordingly, such that each column is positive-skewed. This means that for each column, the sum of cubic elements (i.e., sum(x^3)) are non-negative.

#### Value

an sca object that contains:

loadings	matrix, sparse loadings of PCs.
scores	an n x k matrix, the component scores, calculated using centered (and/or scaled) x. This will only be available when is.cov = FALSE.
cpve	a numeric vector of length k, cumulative proportion of variance in x explained by the top PCs (after center and/or scale).
center	logical, this records the center parameter.
scale	logical, this records the scale parameter.
n.iter	integer, number of iteration taken.
n.obs	integer, sample size, that is, nrow(x).

#### References

Chen, F. and Rohe, K. (2020) "A New Basis for Sparse Principal Component Analysis."

## shrinkage

#### See Also

sma, prs

## Examples

```
## ----- example 1 -----
## simulate a low-rank data matrix with some additive Gaussian noise
n <- 300
p <- 50
k <- 5 ## rank
z <- shrinkage(polar(matrix(runif(n * k), n, k)), sqrt(n))</pre>
b <- diag(5) * 3
y <- shrinkage(polar(matrix(runif(p * k), p, k)), sqrt(p))</pre>
e <- matrix(rnorm(n * p, sd = .01), n, p)</pre>
x <- scale(z %*% b %*% t(y) + e)</pre>
## perform sparse PCA
s.sca <- sca(x, k)</pre>
s.sca
## ----- example 2 -----
## use the `pitprops` data from the `elasticnet` package
data(pitprops)
## find 6 sparse PCs
s.sca <- sca(pitprops, 6, gamma = 6, is.cov = TRUE)</pre>
print(s.sca, verbose = TRUE)
```

shrinkage

Shrinkage

#### Description

Shrink a matrix using soft-thresholding or hard-thresholding.

## Usage

```
shrinkage(x, gamma, shrink = c("soft", "hard"), epsilon = 1e-11)
```

#### Arguments

х	matrix or Matrix, to be threshold.
gamma	numeric, the constraint of Lp norm, i.e. $\ x\  \leq \gamma$ .
shrink	character(1), shrinkage method, either "soft"- (default) or "hard"-thresholding (see details).
epsilon	numeric, precision tolerance. This should be greater than .Machine\$double.eps.

#### Details

A binary search to find the cut-off value.

shrink: The shrink option specifies the shrinkage operator to use. Currently, there are two build-in options—"soft"- and "hard"-thresholding. The "soft"-thresholding universally reduce all elements and sets the small elements to zeros. The "hard"-thresholding only sets the small elements to zeros.

#### Value

a list with two components:

matrix	matrix, the matrix that results from soft-thresholding
norm	numeric, the norm of the matrix after soft-thresholding. This value is close to constraint if using the second option.

#### References

Chen, F. and Rohe, K. (2020) "A New Basis for Sparse Principal Component Analysis."

### Examples

x <- matrix(1:6, nrow = 3)
shrink\_x <- shrinkage(x, 1)</pre>

sma

Sparse Matrix Approximation

## Description

Perform the sparse matrix approximation (SMA) of a data matrix x as three multiplicative components: z, b, and t(y), where z and y are sparse, and b is low-rank but not necessarily diagonal.

#### Usage

```
sma(
    x,
    k = min(5, dim(x)),
    gamma = NULL,
    rotate = c("varimax", "absmin"),
    shrink = c("soft", "hard"),
    center = FALSE,
    scale = FALSE,
    normalize = FALSE,
```

sma

```
order = FALSE,
flip = FALSE,
max.iter = 1000,
epsilon = 1e-05,
quiet = TRUE
```

#### Arguments

)

х	matrix or Matrix to be analyzed.
k	integer, rank of approximation.
gamma	numeric(2), sparsity parameters. If gamma is numeric(1), it is used for both left and right sparsity component (i.e, z and y). If absent, the two parameters are set as (default): $sqrt(nk)$ and $sqrt(pk)$ for z and y respectively, where n x p is the dimension of x.
rotate	character(1), rotation method. Two options are currently available: "varimax" (default) or "absmin" (see details).
shrink	character(1), shrinkage method, either "soft"- (default) or "hard"-thresholding (see details).
center	logical, whether to center columns of x (see scale()).
scale	logical, whether to scale columns of x (see scale()).
normalize	logical, whether to rows normalization should be done before and undone af- terward the rotation (see details).
order	logical, whether to re-order the columns of the estimates (see Details below).
flip	logical, whether to flip the signs of the columns of estimates such that all columns are positive-skewed (see details).
max.iter	integer, maximum number of iteration (default to 1,000).
epsilon	numeric, tolerance of convergence precision (default to 0.00001).
quiet	logical, whether to mute the process report (default to TRUE)

#### Details

rotate: The rotate option specifies the rotation technique to use. Currently, there are two build-in options—"varimax" and "absmin". The "varimax" rotation maximizes the element-wise L4 norm of the rotated matrix. It is faster and computationally more stable. The "absmin" rotation minimizes the absolute sum of the rotated matrix. It is sharper (as it directly minimizes the L1 norm) but slower and computationally less stable.

shrink: The shrink option specifies the shrinkage operator to use. Currently, there are two build-in options—"soft"- and "hard"-thresholding. The "soft"-thresholding universally reduce all elements and sets the small elements to zeros. The "hard"-thresholding only sets the small elements to zeros.

Also, If normalize is a function then it should take x as an argument and return a vector which is used like the vector above.

order: In PCA (and SVD), the principal components (and the singular vectors) are ordered. For this, we order the sparse components (i.e., the columns of z or y) by their explained variance in the data, which is defined as  $sum((x \%\% y)^2)$ , where y is a column of the sparse component. Note: not to be confused with the cumulative proportion of variance explained by y (and z), particularly when y (and z) is may not be strictly orthogonal.

flip: The argument flip gives an indication of if and the columns of estimated sparse component should be flipped. Note that the estimated (sparse) loadings, i.e., the weights on original variables, are column-wise invariant to a sign flipping. This is because flipping of a principal direction does not influence the amount of the explained variance by the component. If flip=TRUE, then the columns of loadings will be flip accordingly, such that each column is positive-skewed. This means that for each column, the sum of cubic elements (i.e., sum(x^3)) are non-negative.

#### Value

an sma object that contains:

z, b, t(y)	the three parts in the SMA. z is a sparse n x k matrix that contains the row
	components (loadings). The row names of z inherit the row names of x. b is a k
	x k matrix that contains the scores of SMA; the Frobenius norm of b equals to
	the total variance explained by the SMA. y is a sparse n x k matrixthat contains
	the column components (loadings).
The row names of	f y inherit the column names of x.

score the total variance explained by the SMA. This is the optimal objective value obtained.

n.iter integer, the number of iteration taken.

#### Examples

```
## simulate a rank-5 data matrix with some additive Gaussian noise
n <- 300
p <- 50
k <- 5 ## rank
z <- shrinkage(polar(matrix(runif(n * k), n, k)), sqrt(n))
b <- diag(5) * 3
y <- shrinkage(polar(matrix(runif(p * k), p, k)), sqrt(p))
e <- matrix(rnorm(n * p, sd = .01), n, p)
x <- scale(z %*% b %*% t(y) + e)</pre>
```

soft

```
## perform sparse matrix approximation
s.sma <- sma(x, k)
s.sma</pre>
```

soft

Soft-thresholding

## Description

Perform soft-thresholding given the cut-off value.

#### Usage

soft(x, t)

## Arguments

х	any numerical matrix or vector.
t	numeric, the amount to soft-threshold, i.e., $sgn(x_{ij})( x_{ij}-t )_+$ .

## Description

This is a re-implementation of stats::varimax, which (1) adds a parameter for the maximum number of iterations, (2) sets the default normalize parameter to FALSE, (3) outputs the number of iteration taken, and (4) returns regular matrix rather than in loadings class.

## Usage

varimax(x, normalize = FALSE, eps = 1e-05, maxit = 1000L)

## Arguments

х	A loadings matrix, with $p$ rows and $k < p$ columns
normalize	logical. Should Kaiser normalization be performed? If so the rows of $x$ are re-scaled to unit length before rotation, and scaled back afterwards.
eps	The tolerance for stopping: the relative change in the sum of singular values.
maxit	integer, maximum number of iteration (default to 1,000).

23

## Value

A list with three elements:

rotated	the rotated matrix.
rotmat	the (orthogonal) rotation matrix.
n.iter	the number of iterations taken.

stats::varimax

varimax.criteria The varimax criterion

## Description

Calculate the varimax criterion

#### Usage

varimax.criteria(x)

## Arguments ×

a matrix or Matrix.

#### Value

a numeric of evaluated varimax criterion.

## References

Varimax rotation (Wikipedia)

## Examples

```
## use the "swiss" data
fa <- factanal( ~., 2, data = swiss, rotation = "none")
lds <- loadings(fa)
## compute varimax criterion:
varimax.criteria(lds)
## compute varimax criterion (after the varimax rotation):
rlds <- rotation(lds, rotate = "varimax")
varimax.criteria(rlds)</pre>
```

vgQ.absmin

## Description

This is a helper function for absmin and is not to be used directly by users.

## Usage

```
vgQ.absmin(x)
```

## Arguments

х

a matrix or Matrix, initial factor loadings matrix for which the rotation criterian is to be optimized.

## Value

a list required by GPArotation::GPForth for the absmin rotation.

## Examples

## Not run: ## NOT RUN ## NOT for users to call.

## End(Not run)
